libShower

Manual
V0.1
frank.meisel@lhep.unibe.ch

Description

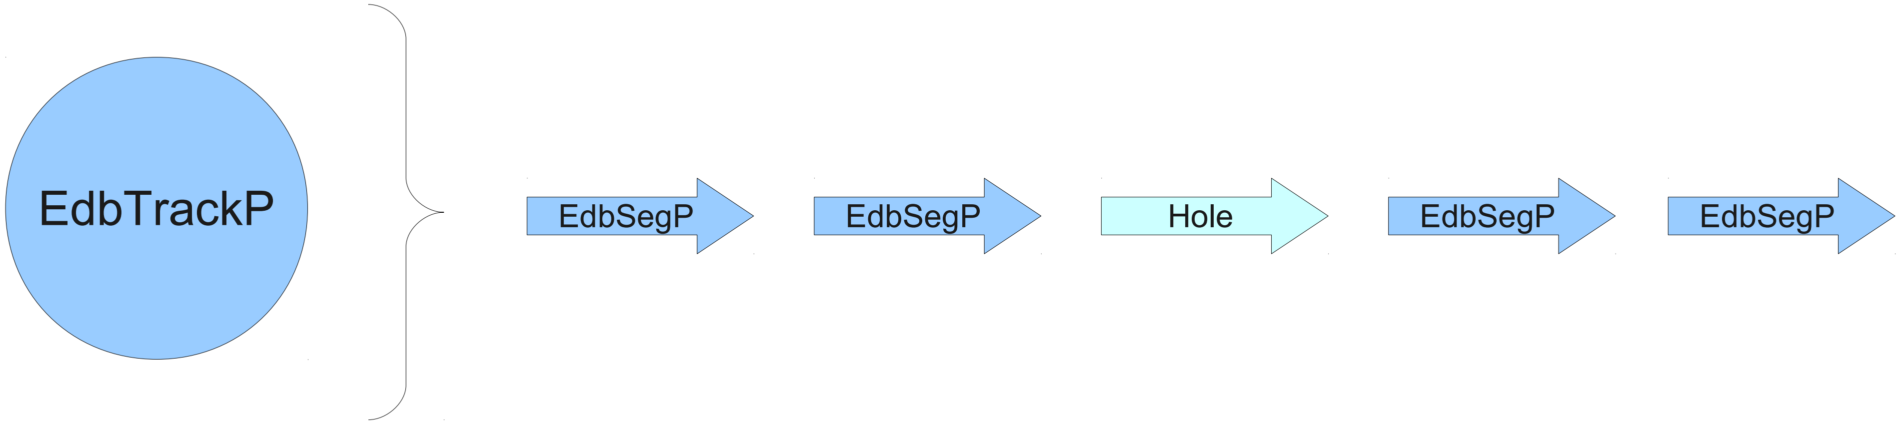
- **This manual is intended to make the user familiar on the way showers are dealt with.**
- **The user should not bother about details.**
- **To increase the performance, the user may give additional information on the date to obtain a better result.**

Overview

- Shower for Event classification.
- Shower characteristics
- Shower implementation in FEDRA
-

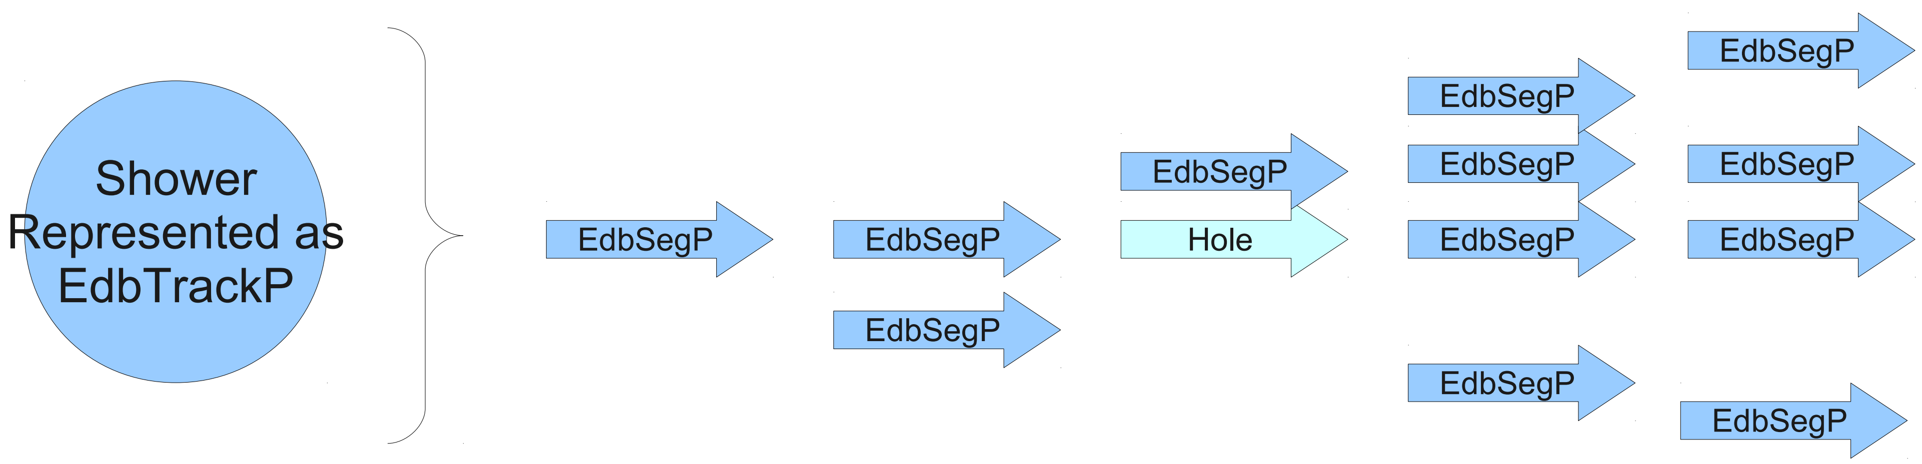
Object description

- A track in fedra
  - One Segment Per Plate
  - N(), Npl(), N0, Theta(), XYZ, P()



Object description

- A shower in fedra
  - Can have *More* than One Segment Per Plate
  - N(), Npl(), N0, Theta(), XYZ, P()
  - Plus additional information: *longitudinal&transversal* Profile!



Object description

Due to backward compabilities we have to use this way.
This is a pain in the back... :-)

- Using EdbTrackP as object class for Shower is ok, but we lose physical information.
- Compensated by infos in EdbShowerAlgE...
  - May be put later in a extra *EdbShowerP* class...
- Up to now: how is a shower represented/stored?
- We have Shower.root which uses a TTree to store the variables. Technically equivalent to do storage like EdbTrackP, but it requires complex I/O conversions to get from
  - TTree entry ↔ EdbTrackP

What is to be done for showers?

- In case we have scanback done, vertex found, scanforth done (hadr. re-interaction), we need for the full description of the event some other information: showers?
- Why are showers for the event classification important?
- Electrons: nu_e from beam; tau->e;
- Photons: present in almost any event, mainly through the decay of:
- Pi0: Find two photons, match them in case of more

Finding showers

- Showers are either attached to vertex directly or indirectly:
  - Electrons: start to shower direct from the vertex without flight length; IP to vertex rather small; DeltaZ to vertex very small.
  - Photons: fly – then showering happens; therefore IP to vertex bigger than attached tracks; DeltaZ to vertex can be large (mean flight length ca10plates).
- Finding a electron shower can be easier than photon shower (directly attached track or BT)

Properties of Showers

- We need to be sure of the following things.
- We have to find the shower (start)
- We have to reconstruct (collect all the tracks) it having as much of it reconstructed as possibles (lowest loss as possible).
- After shower(s) found and reconstructed we need the main properties:
  - Energy
  - ID
  - 1ry-2ry vtx attachment

Properties of the `Shower.root` file.
a) basic quantities

Name in `Shower.root`	Description	Analogy in EdbTrackP
number_eventb/I	MC event number	->MCEvt()
sizeb	Number of Basetracks	N()
nfilmb[]	Plate ID of BT[i]	??(to be looked up)
lengthfilmb	Number of Plates Crossed	Npl()
x,y,z -b[]	X,Y,Z Coordinates of BT[i]	->X(),Y(),Z()
tx,ty -b[]	TX,TY Coordinates of BT[i]	->TX(),TY()
plateb -b[]	??(to be looked up)	??(to be looked up)
Numbereventb[]	Numbereventb[]	Numbereventb[]
showerID/I	showerID/I	showerID/I
isizeb/I	isizeb/I	isizeb/I
ntrace1simu[sizeb]/I	ntrace1simu[sizeb]/I	ntrace1simu[sizeb]/I
ntrace2simu[sizeb]/I	ntrace2simu[sizeb]/I	ntrace2simu[sizeb]/I
ntrace3simu[sizeb]/I	ntrace3simu[sizeb]/I	ntrace3simu[sizeb]/I
Ntrace4simu[sizeb]/I	Ntrace4simu[sizeb]/I	Ntrace4simu[sizeb]/I
chi2btkb[sizeb]/F	chi2btkb[sizeb]/F	chi2btkb[sizeb]/F

Properties of the `Shower.root` file. b) derived quantities

Name in `Shower.root`	**Description**	**Analogy in EdbTrackP**
number_eventb/I	number_eventb/I	number_eventb/I
sizeb	sizeb	sizeb
nfilmb[]	nfilmb[]	nfilmb[]
lengthfilmb	lengthfilmb	lengthfilmb
x,y,z -b[]	x,y,z -b[]	x,y,z -b[]
tx,ty -b[]	tx,ty -b[]	tx,ty -b[]
plateb -b[]	plateb -b[]	plateb -b[]
Numbereventb[]	Numbereventb[]	Numbereventb[]
showerID/I	showerID/I	showerID/I
isizeb/I	isizeb/I	isizeb/I
ntrace1simu[sizeb]/I	ntrace1simu[sizeb]/I	ntrace1simu[sizeb]/I
ntrace2simu[sizeb]/I	ntrace2simu[sizeb]/I	ntrace2simu[sizeb]/I
ntrace3simu[sizeb]/I	ntrace3simu[sizeb]/I	ntrace3simu[sizeb]/I
Ntrace4simu[sizeb]/I	Ntrace4simu[sizeb]/I	Ntrace4simu[sizeb]/I
chi2btkb[sizeb]/F	chi2btkb[sizeb]/F	chi2btkb[sizeb]/F

Reconstruction: Mode A

- Choose Initiator Basetracks:

```
ShowerInstance = new EdbShowerRec();
ShowerInstance-> SetInBTArray(TObjArray* InBTArray);
```

- Set the PVR object on which the reconstruction shall operate:

```
ShowerInstance-> SetEdbPVRec(EdbPVRec* Ali);
```

- Start Reconstruction

```
ShowerInstance-> Execute();
```

- Retrieve Reconstructed Shower Array

```
ShowerInstance-> GetRecoShowerArray();
```

Reconstruction: Mode B Frederics Algo Implementation

- To be filled and explained...:
- void recdown(int num, int MAXPLATE, int DATA, int Ncand, double* x0, double* y0, double* z0, double* tx0, double* ty0, double* chi20, int* W0, double* P0, int* Flag0, int* plate0, int* id0, int* TRid, double* Esim, int piece2, int piece2par)

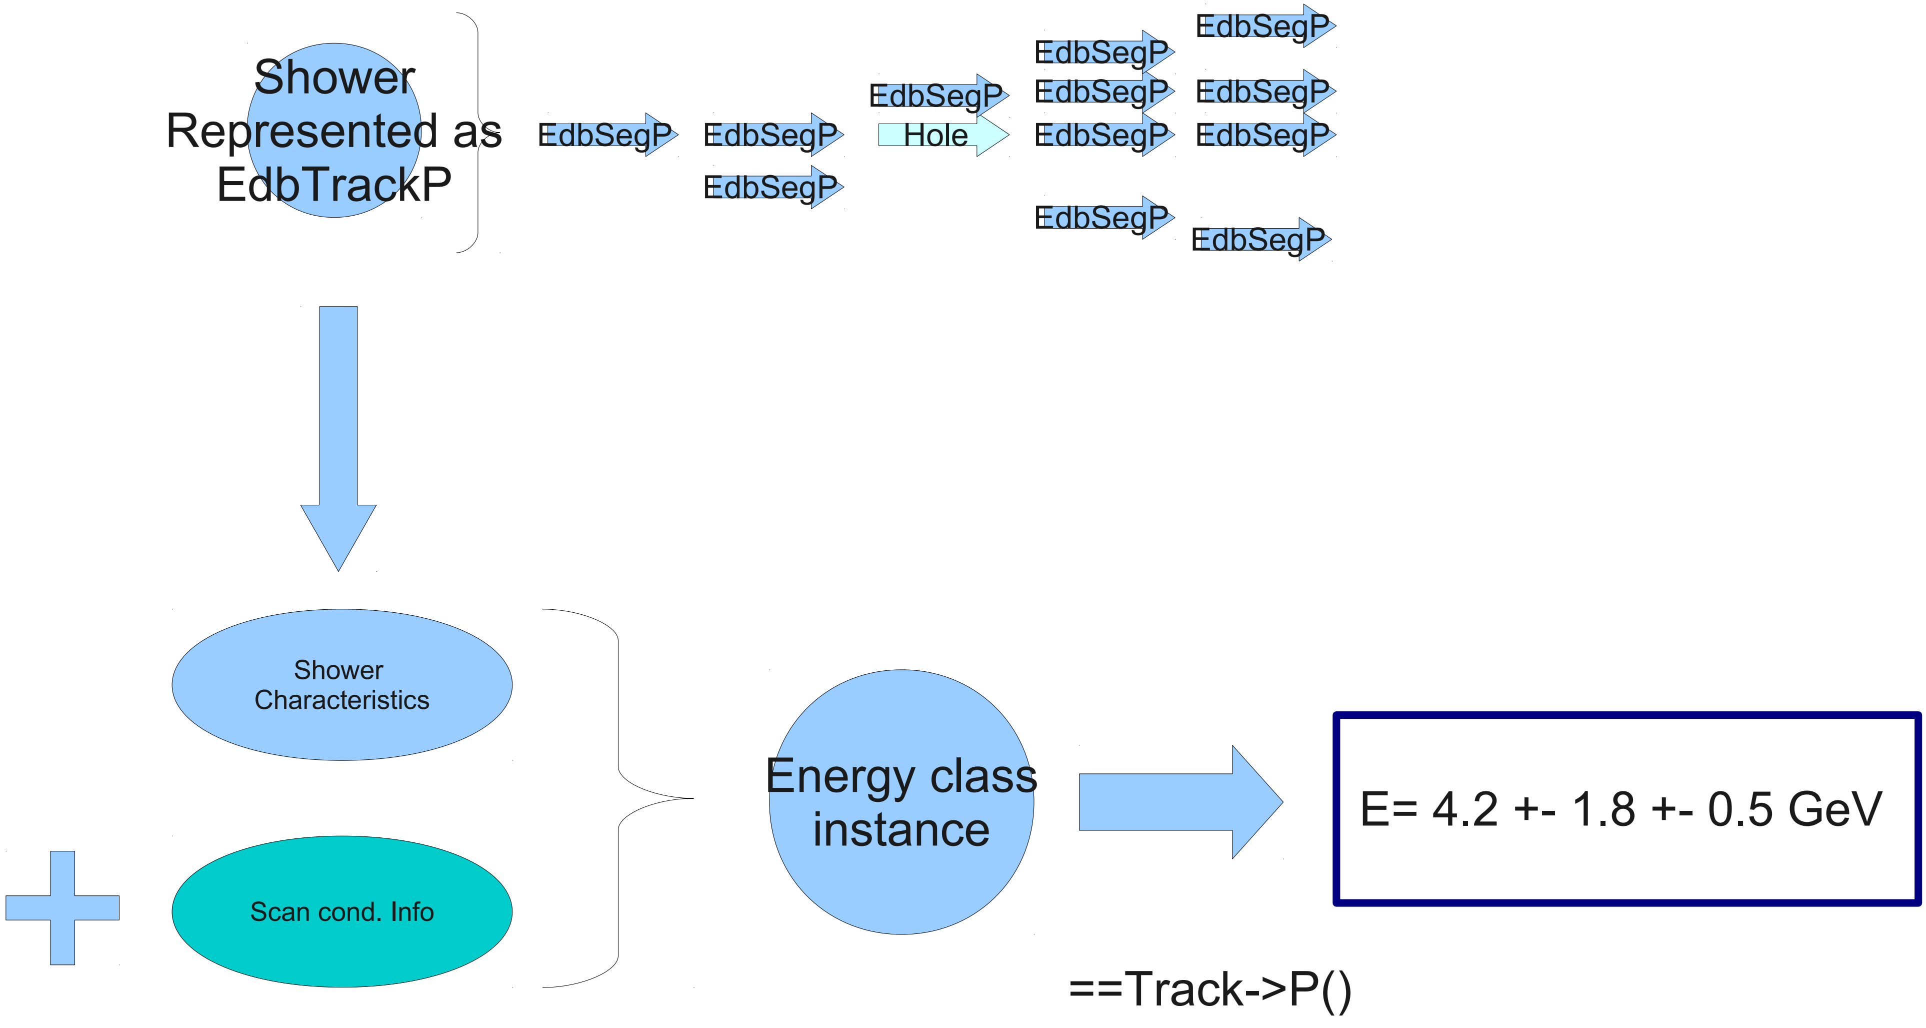
Shower Energy Measurement

- The Shower Energy is measured using:
  - Basic Properties of the Shower
  - Conditions from Brick Scanning

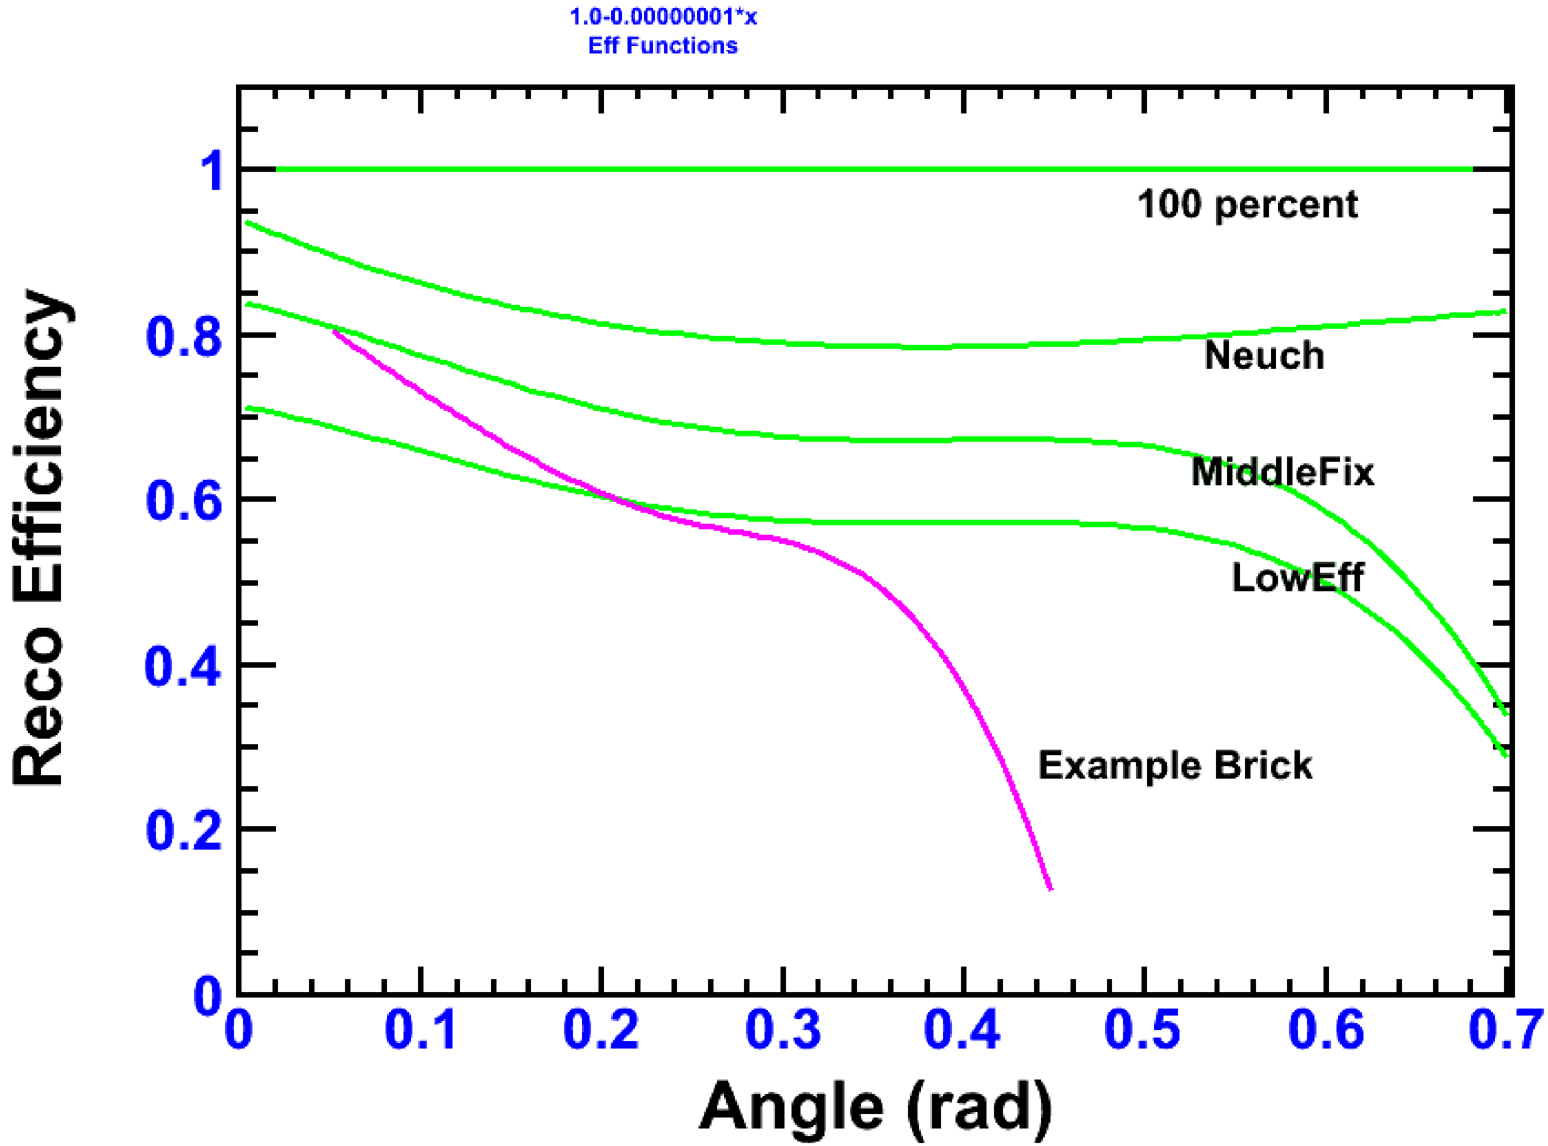
- Shower Properties
  - Shape
  - Density
  - Angle

- Scan Conditions
  - Reco Efficiency
  - BG Level

Block diagram: energy



Implemented ScanEfficiencies



Example Brick: Bern 144320, Mic4

Energy: Technical

- Get Reconstructed Shower Array
- Start Energy Estimation
- Retrieve Reconstructed Shower Array, with P() filled.

```
// Instantate ShowerAlgorithmEnergy Class
EdbShowerAlgESimple* ShowerAlgEnergyInstance = new EdbShowerAlgESimple();

// Run Shower Energy Algorithm on all shower/tracks
ShowerAlgEnergyInstance->DoRun(RecoShowerArray);

// All tracks contain now in P() the estimated energy.
```

Energy: stat. Results: sigma(E)/E gamma

Interpolation

- Interpolate energy statistic uncertanties with ROOT Tspline3 class (between energies)
- (No interpolation done between plate binnings.)

More here : SYSTEMATICS

- Calculating energy gives you stat. AND sys. On the screen. Saved is then the quadratic sum.
  - (Attention: at the moment (svn1056) in fedra there is no additional variable to store momentum/energy error of a track/shower. Uncertainty is now ***only*** written in shower.root file.)
- Different sources have been investigated.
- See the following table for an overview.
  - (Details will be written up in the thesis, also many plots and tables; *explanations will follow here*)

E: Systematics: Addition

- As we know, systematic sources are neither totally independent nor totally dependent...
- But to derive an analytical form for the covariance elements is even more impossible in experimental cases (no analytical function to describe the dependencies)
- To calculate ALL variations by means of MC estimates would require tooo much computing power.
- So tradeoff here: take the sources listed in table and add them
  - *Q*uadratically: sigma^sys_tot= *Q*SUM(sigma^sys_i)
  - *L*inear: sigma^sys_tot= *L*SUM(sigma^sys_i)
- „True“ error will be in between....
- The more systematic sources considered, the larger the error we get.
- We think that the most important we have investigated...

Shower ID

- Problem:
  - One single Shower can originate from either photons, electrons or ($_{\text{charged}}$) pions

- Solution:
  - Shower ID class, which does a differentiation!

- Technicalities:
  - The ID class determines Shower from its originating particle

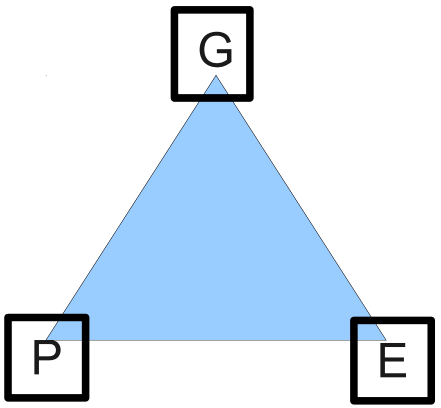
Shower ID

- Instead of assigning the ANN one number for
  - Gamma, Electron, Pion(+-)
- We do decions based on „X vs Y“, i.e.
  - Gamma vs Electron
  - Electron vs Pion
- Because the ANN is better in discriminating two-by-two variable discrimination.
- In continuation with former implementations, we save these results in eProb1,eProb90_X_vs_Y

Eprob1: bg rejection at 1%

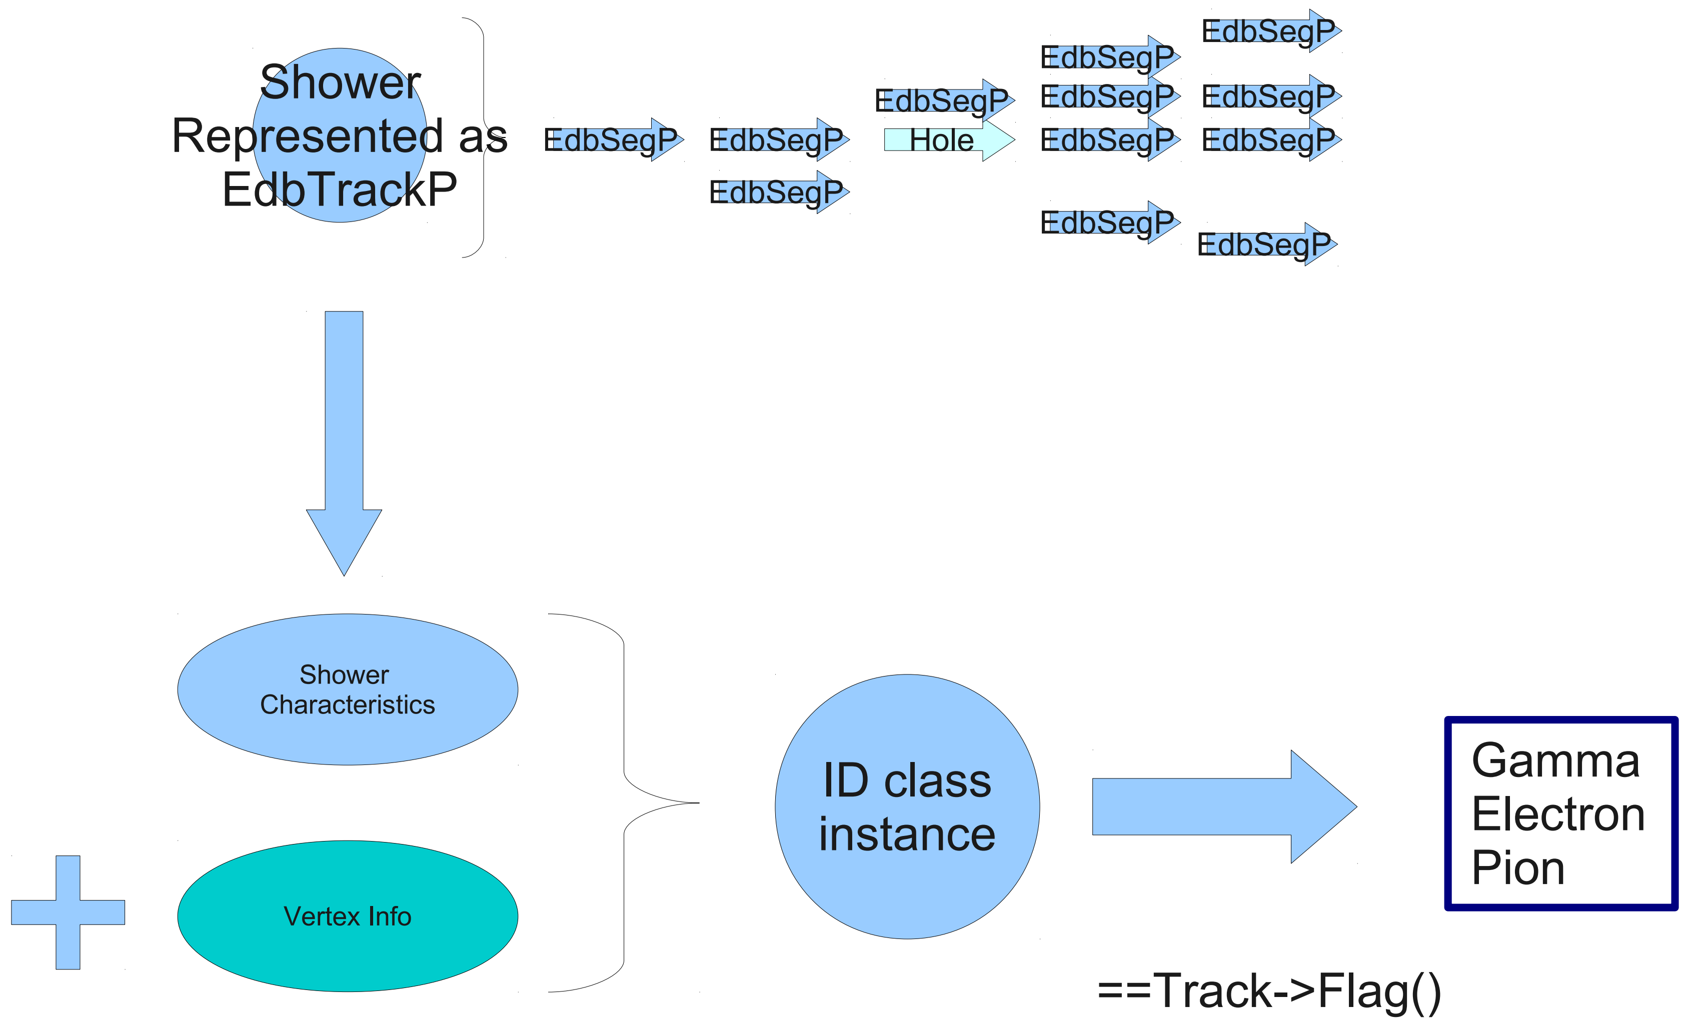
Eprob90: signal efficiency 90%

Shower ID



- Two type of variables:
  - SHID: 0(G),1(E),2(P)
  - SPID: 0,1,2
  - So we can assign a unique
  - ID for each combination:
  - Example:
    - gamma_vs_e: SHID=0,SPID=1
    - e_vs_pi: SHID=1,SPID=2
  - Always put 0 if it belongs to Type 0 (SHID)
  - Always put 1 if it belongs to Type 1 (SPID)

Block diagram: ID



More here...

The Cleaning of High BG level...

- We try to keep a constant BT density level of not more than 40BT/mm2
- To get this, we have the EdbPVRec patterns object, which we use for checks:
- We calculate BT density plate by plate and can adapt the Quality Cut plate by plate accordingly.

EdbPVRQuality

- This class does BG cleaning... How it works:
- EdbPVRQuality* Qualityobject = new EdbPVRQuality(gAli);
  - gAli is the filled EdbPVRec object. Usually this implicates the data coming from cp.root files.
  - LinkedTracks.root EdbPVRec object usually is already very „clean“, i.e. that linked tracks are often „good“ (physically) objects.
- Qualityobject->Print();
- Qualityobject->Help();
